I. IDENTIFICATION AND DEFINITION OF CASES

Clinical Description: A bacterial disease caused by organisms in the *Mycobacterium tuberculosis* complex (*M. tuberculosis*, *M. bovis*, *M. africanum*, *M. canettii*, *M. microti*, *M. caprae* and *M. pinnipedii*). There are two forms of TB, latent and active (pulmonary and/or extrapulmonary).

Latent TB infection can be established following exposure to an infectious patient expelling aerosolized particles containing viable bacilli. Initial infection generally causes no outward clinical manifestations and is called latent TB. It is characterized by microscopic lesions in the lungs that commonly heal, leaving no residual changes other than occasional small pulmonary or tracheobronchial lymph node calcifications.

Active TB disease can develop following infection and is facilitated by certain risk factors. It can be pulmonary and/or extrapulmonary. Active pulmonary TB may arise from reactivation of a latent focus originating from the initial subclinical infection or from re-infection. Extrapulmonary TB occurs in 14%-35% of cases and may affect any organ or tissue as follows: lymph nodes (44%), pleura (20%), genitourinary tract (4%), bones and joints (10%), meninges (4%), gastrointestinal tract and peritoneum (10%), and other locations including skin, eyes and other organs and disseminated disease (11%).

Cough, fever, fatigue, night sweats, and weight loss are common symptoms associated with pulmonary TB. In most cases, cough is initially nonproductive and later accompanied by purulent sputum. Symptoms such as hemoptysis and hoarseness associated with laryngeal TB are sometimes prominent in advanced stages. Chest radiography reveals pulmonary infiltrates and cavitations in the upper segments of the lung lobes. In prolonged disease, fibrotic changes with volume loss are seen.

A. Laboratory Criteria:
- Isolation of *M. tuberculosis* in culture from a clinical specimen, OR
- Detection of *M. tuberculosis complex* from a clinical specimen by nucleic acid amplification test.

B. Wisconsin Surveillance Case Definition:
- Confirmed: A case that meets the clinical case definition OR is laboratory-confirmed.
- Suspected: An illness marked by symptoms and laboratory tests that may be indicative of tuberculosis, such as a prolonged cough, prolonged fever, hemoptysis, compatible radiographic findings or other appropriate medical imaging findings.

II. REPORTING

A. Wisconsin Notifiable Disease Category I – Methods for Reporting: This disease shall be reported IMMEDIATELY BY TELEPHONE to the patient’s local health officer or to the local health officer’s designee upon identification of a case or suspected case, per Wis. Admin. Code § DHS 145.04 (3) (a). In addition to the immediate report, complete and fax, mail or electronically report an Acute and Communicable Diseases Case Report (DHS F-44151) to the address on the form, or enter the data into the Wisconsin Electronic Disease Surveillance System, within 24 hours.

B. Responsibility for Reporting: According to Wis. Admin. Code § DHS 145.04(1), persons licensed under Wis. Stat. ch. 441 or 448, laboratories, health care facilities, teachers, principals, or nurses serving a school or daycare center, and any person who knows or suspects that a person has a communicable disease identified in Appendix A.
C. **Clinical Criteria for Reporting:** If there is no positive culture or nucleic acid amplification test to confirm TB, a person may be considered to have clinical TB. A clinical case must meet the following criteria:

- Treatment for TB disease with two or more medications, and improvement in signs and/or symptoms after at least two months of treatment.
- Completed diagnostic evaluation.
- Signs and symptoms compatible with tuberculosis (TB) (e.g., abnormal chest radiograph, abnormal chest computerized tomography scan or other chest imaging study, clinical evidence of current disease or high suspicion) and any combination of the following criteria:
  - A positive tuberculin skin test or positive interferon gamma release assay for *M. tuberculosis*.
  - Risk factors as below:
    - Birth in a country having a high TB prevalence/incidence.
    - Exposure to a known case of tuberculosis.
    - Age ≤ 5 years and exposure to a known case of tuberculosis.
    - History of previous complete or partial treatment for tuberculosis.
    - HIV infection.
    - Children or adolescents with parents born in a country with a high prevalence of TB cases.
    - Locally defined, high-risk groups with any of the following socioeconomic predictors: low income, inner-city residence, migrant labor, drug and/or alcohol abuse, homeless.
    - Immunosuppressive therapy (including immunomodulators for arthritis, Crohn’s, or other autoimmune disease).
    - Chronic renal failure.
    - Hematologic disorders such as leukemia or lymphoma.
    - Malignant neoplasms such as carcinoma of the head or neck.
    - Residency or occupation in high-risk congregate settings.
    - Gastrectomy or jejunoileal bypass.
    - Fibrotic changes or “old healed TB” on CXR
    - Diabetes mellitus.
    - Pulmonary silicosis.
    - Unexplained ≥ 10% ideal weight loss.

D. **Laboratory Criteria for Reporting:**

- Isolation of *M. tuberculosis* in culture from a clinical specimen, OR
- Detection of *M. tuberculosis* complex from a clinical specimen by nucleic acid amplification test.

III. **CASE INVESTIGATION**

A. **Responsibility for case investigation:** It is the responsibility of the local health department (LHD) to investigate or arrange for investigation of suspected or confirmed cases as soon as is reasonably possible. A case investigation may include information collected by phone, in-person, in writing, or through review of medical records or communicable disease report forms, as necessary and appropriate.

B. **Required Documentation:**

1. Enter case investigation information into the Wisconsin Electronic Disease Surveillance System (WEDSS).
2. A Report of Verified Case of Tuberculosis (Centers for Disease Control and Prevention form) will be available in WEDSS upon receipt of a confirmed case.

C. **Additional Investigation Responsibilities:** If requesting state-funded medication, fill out the Antituberculosis Therapy Program Initial Request for Medication (F-44000).

IV. **PUBLIC HEALTH INTERVENTIONS AND PREVENTION MEASURES**

B. Protocol for Disease Management and Investigation of Contacts

- For patients with pulmonary, pleural, and laryngeal tuberculosis, control of infectivity is best achieved by prompt specific drug therapy. Collection of three sputum samples, either by spontaneous production or induction, is required.
- Persons with extrapulmonary TB should receive a complete medical examination and provide three sputum samples for testing to assure that the TB is not disseminated to other parts of the body and/or to the lungs or larynx (which would make them infectious). Pulmonary symptoms are not required for pulmonary TB to be present.
- Patients with pulmonary, pleural, or laryngeal TB must remain isolated (at home or in an airborne isolation room designated for TB patients) until three consecutive smears are negative for AFB from sputum specimens, each collected at least eight (8) hours apart; AND the patient has been on appropriate therapy for at least two weeks; AND there is evidence of clinical improvement, OR another cause for the signs and symptoms has been identified.
- If three AFB smear positive sputum specimens are tested, and there is a negative nucleic acid amplification test result, AND the patient is asymptomatic, the patient may be released from isolation as minimally infectious. Such a person may, however, still have active TB, and the case may not be closed until final culture results are available and negative for \textit{M. tuberculosis} complex. The decision to release the patient from isolation must be balanced by the potential need for a more extensive contact investigation should the patient have pulmonary TB.
- Multiple-Drug Resistant (MDR) pulmonary or laryngeal cases must remain in isolation until three consecutive cultures (not smears) are negative for MTB from sputum specimens collected on different days.

C. Investigation of Contacts and Identification of the Source of Infection

Initial interferon gamma release assay or tuberculin skin testing of all household members and other close contacts, with repeat testing of those with negative tests 90 days post-exposure.

D. Prevention Measures

- Prevention of the spread of tuberculosis is achieved by:
  - Rapid recognition of TB disease.
  - Isolation of the person with TB disease until no longer infectious, as proven by sputum smears and cultures.
  - Appropriate, completed, and directly observed therapy of the person with TB disease.
  - Timely, complete, and appropriate treatment for those exposed to the person with active disease, including:
    - Directly observed preventive therapy of all children and immunosuppressed persons in contact with the person with confirmed or suspect TB disease. This therapy should begin IMMEDIATELY UPON IDENTIFICATION of these persons as contacts, and should continue as the contacts are tested for active disease, and until final testing is complete and negative, 10–12 weeks after the last exposure to the infectious person.
    - Identification and testing of as many high- and medium-priority contacts as can be identified.
    - Appropriate and completed treatment of any contacts who are identified as having TB infection, but ONLY after they have been shown not to have active TB disease, as determined by:
      - Chest X-ray
      - Medical evaluation, and in the event of any respiratory symptoms OR abnormal chest X-ray results, smear and culture of three respiratory specimens: Collect a series of three sputum specimens, 8-24 hours apart with, at least one being an early morning specimen.
  - No single intervention is sufficient to control the spread of tuberculosis; a coordinated approach and usually more than one person are necessary. Please consult the state TB Program when you have a person with confirmed or suspected TB.
V. CONTACTS FOR CONSULTATION
   A. Local health departments and tribal health agencies:
